

Aegis (Shield of Zeus & Athena) – Fraud Detection Overview

1. Introduction

Aegis is building an AI-powered fraud detection and credit scoring system for mobile money users in Africa. Millions rely on mobile money without access to traditional banks. Fraud is on the rise, so trust and safety are our first focus. This document outlines how transactions flow through Aegis and how fraud detection works.

2. What is a Transaction?

A transaction represents the transfer of money/value between parties. Examples: customer-to-customer, customer-to-merchant, wallet deposits/withdrawals. Each transaction contains sender, receiver, amount, currency, timestamp, reference ID, and the full raw payload (from the mobile money provider).

3. What Makes a Transaction Suspicious?

Fraud can be flagged based on rule-based checks and later AI/ML models: - High-value transfers (above threshold) - Too many transactions in short time (velocity checks) - Blacklisted accounts - Geographic or behavioral anomalies - Structuring: splitting large transfers into many small ones

4. Technical Flow (for Engineers)

This diagram shows how mobile money providers connect to Aegis via webhooks, how transactions are stored, rules applied, and alerts generated. AI/ML models can be added later for advanced detection.

5. Non-Technical Flow (for Storytelling)

This diagram explains Aegis in simple terms: money comes in, we check it for safety, if safe it passes, if suspicious we raise an alert and notify the user/admin. This is how we build trust and protect users.

6. Why This Matters

Financial inclusion is only possible when people trust the system. By detecting fraud in real-time, Aegis makes digital finance safer. This foundation prepares us to later add AI-driven credit scoring to unlock loans for the unbanked.
